# Outline

Introduction

Periodic Traversal

References

# Introduction

- ▶ The graph traversal problem requires an algorithm that starts on an arbitrary vertex, and moves along edges to eventually visit every vertex of the graph.

# Introduction

- ▶ The graph traversal problem requires an algorithm that starts on an arbitrary vertex, and moves along edges to eventually visit every vertex of the graph.
- ▶ Trivial memory lower bound for graph traversal  $\Omega(\log n)$ . We wish to achieve this lower bound whenever possible.

# Introduction

- ▶ Trivial memory lower bound for graph traversal  $\Omega(\log n)$ . We wish to achieve this lower bound whenever possible.
- ▶ Model of Computation is a Finite Automaton that only knows local information of the graph

# Introduction

- ▶ The graph traversal problem requires an algorithm that starts on an arbitrary vertex, and moves along edges to eventually visit every vertex of the graph.
- ▶ Trivial memory lower bound for graph traversal  $\Omega(\log n)$ . We wish to achieve this lower bound whenever possible.
- ▶ Model of Computation is a Finite Automaton that only knows local information of the graph
- ▶ There are two main classes of graphs, anonymous graphs and labelled graphs.

# Anonymous Graphs

- ▶ A graph that does not have a unique label for every vertex is called an anonymous graph.

# Anonymous Graphs

- ▶ A graph that does not have a unique label for every vertex is called an anonymous graph.
- ▶ In anonymous graphs, we allow edges at an incident vertex to be distinguishable from one another, called a *local orientation* of the graph, represented by port numbers

# Motivation

## ► Theorem

*(Fraigniaud et. al., 2005) For any finite automaton with  $K$  states, and any  $d \geq 3$ , there exists an anonymous planar graph  $G$  of maximum degree  $d$  with at most  $K + 1$  vertices that the finite automaton cannot traverse.*

# Motivation

## ► Theorem

*(Fraigniaud et. al., 2005) For any finite automaton with  $K$  states, and any  $d \geq 3$ , there exists an anonymous planar graph  $G$  of maximum degree  $d$  with at most  $K + 1$  vertices that the finite automaton cannot traverse.*

- What if the local orientation is not arbitrary?

# Definition

- ▶ Periodic graph traversal requires that an algorithm visits every vertex infinitely many times in a periodic manner

# Definition

- ▶ Periodic graph traversal requires that an algorithm visits every vertex infinitely many times in a periodic manner
- ▶ The period of a traversal on a graph with  $n$  vertices is the maximum number of edge traversals performed between two consecutive visits of a generic vertex, denoted by  $\pi(n)$

# Previous Results

## ► Theorem

*(Dobrev et. al., 2005) If  $G$  is an anonymous graph on  $n$  vertices, there exists a local orientation and a corresponding robot (with 1 state) that will periodically traverse  $G$  with period  $\pi(n) \leq 10n$*

## ► Theorem

*(Ilcinkas, 2008) If  $G$  is an anonymous graph on  $n$  vertices, there is a local orientation and a robot (with 3 states) that will periodically traverse  $G$  with period  $\pi(n) \leq 4n - 2$*

## ► Theorem

*(Gąsieniec et. al., 2008) If  $G$  is an anonymous graph on  $n$  there is a local orientation of  $G$  and a robot (with 11 states) that will periodically traverse  $G$ , with period  $\pi(n) \leq 3.75n - 2$*

# Lower Bound

- ▶ If  $G$  is an anonymous graph on  $n$  vertices, the lower bound of the period of any periodic traversal is  $\pi(n) \geq 2n - 2$
- ▶ In particular, trees achieve this bound

# Lower Bound

- ▶ If  $G$  is an anonymous graph on  $n$  vertices, the lower bound of the period of any periodic traversal is  $\pi(n) \geq 2n - 2$
- ▶ In particular, trees achieve this bound
- ▶ We wish to find a class of graphs (other than trees) that achieves the lower bound of  $2n - 2$

# Classes of Graphs

- ▶ Let  $G$  be a  $P_3$ -free graph with  $\delta(G) \geq 2$

# Classes of Graphs

- ▶ Let  $G$  be a  $P_3$ -free graph with  $\delta(G) \geq 2$

- ▶ **Lemma**

*Let  $G$  be a graph with  $n$  vertices such that  $G$  is  $P_3$ -free. Then either  $G$  is 2-connected, or  $\Delta(G) = n - 1$ .*

# Robot

- ▶ The robot (finite automaton) has only one state, and it traverses the graph simply by following increasing port numbers

# Robot

- ▶ The robot (finite automaton) has only one state, and it traverses the graph simply by following increasing port numbers
- ▶ The robot will start on any vertex  $v$
- ▶ Initially, the robot will leave  $v$  on the edge with port  $d(v)$
- ▶ At each subsequent vertex  $v$ , if the robot enters  $v$  on port  $i < d(v)$ , it will leave on the edge with port  $i + 1$
- ▶ Similarly, if the robot enters  $v$  on port  $d(v)$ , it backtracks along the same edge (with port  $d(v)$ )

$$\Delta(G) = n - 1$$

- ▶ Let  $v$  be a vertex of degree  $n - 1$
- ▶ Since  $\delta(G) \geq 2$ ,  $v$  has two neighbours  $x$  and  $y$  that are adjacent

$$\Delta(G) = n - 1$$

- ▶ Let  $v$  be a vertex of degree  $n - 1$
- ▶ Since  $\delta(G) \geq 2$ ,  $v$  has two neighbours  $x$  and  $y$  that are adjacent
- ▶ The assignment of port numbers handles all vertices the same except for these three, as shown in the following example

$$\Delta(G) = n - 1$$

$$\Delta(G) = n - 1$$

## 2-connected graphs

### ► Theorem

(Fleishner, 1974) *If  $G$  is 2-connected, then  $G^2$  has a Hamiltonian cycle*

- Let  $H$  be a Hamiltonian cycle of  $G^2$

## 2-connected graphs

### ► Theorem

(Fleishner, 1974) *If  $G$  is 2-connected, then  $G^2$  has a Hamiltonian cycle*

- Let  $H$  be a Hamiltonian cycle of  $G^2$
- The main idea is to create a closed walk  $H^*$  based on  $H$  that visits every vertex of  $G$  using only edges of  $G$
- Then arrange port numbers so the robot will follow  $H^*$
- For our purposes, we will work with the *symmetric orientation* of  $G$  and  $G^2$ , denoted  $\vec{G}$  and  $\vec{G}^2$ , respectively

## 2-connected graphs

- ▶ For every virtual edge of  $H$ , we assign a real path of length two, called a relay path

## 2-connected graphs

- ▶ For every virtual edge of  $H$ , we assign a real path of length two, called a relay path
- ▶ If  $P$  is a maximal virtual path in  $H$  containing more than one vertex, such that all virtual arcs of  $P$  share a common relay vertex  $w$ , then the subgraph  $W$  of  $\vec{G}^2$  consisting of  $P$ , and the relay path of every arc of  $P$ , is called a *wedge*
- ▶ The *size* of  $W$ , denoted  $s(W)$ , is the number of vertices of  $P$

## 2-connected graphs

- ▶ We prove several lemmas related to wedges, the following describes how two wedges can interact

- ▶ **Lemma**

*Suppose  $W_1$  and  $W_2$  are distinct wedges. Then*

- (i) The wedges  $W_1$  and  $W_2$  have no virtual arcs in common.*
- (ii) The wedges  $W_1$  and  $W_2$  have no ribs in common.*

## 2-connected graphs

- ▶ Given a vertex  $v$ , let  $(x, v)$  and  $(v, y)$  be the two arcs of  $H$  incident with  $v$ .

## 2-connected graphs

- ▶ Given a vertex  $v$ , let  $(x, v)$  and  $(v, y)$  be the two arcs of  $H$  incident with  $v$ .
- ▶ The incoming arc of  $v$  is either  $(x, v)$  if it is real, or the real arc  $(w, v)$ , where  $w$  is the relay vertex of  $(x, v)$

## 2-connected graphs

- ▶ Given a vertex  $v$ , let  $(x, v)$  and  $(v, y)$  be the two arcs of  $H$  incident with  $v$ .
- ▶ The incoming arc of  $v$  is either  $(x, v)$  if it is real, or the real arc  $(w, v)$ , where  $w$  is the relay vertex of  $(x, v)$
- ▶ Similarly, the outgoing arc of  $v$  is either  $(v, y)$  if it is real, or the real arc  $(v, w)$ , where  $w$  is the relay vertex of  $(v, y)$ .

## 2-connected graphs

- ▶ Given a vertex  $v$ , let  $(x, v)$  and  $(v, y)$  be the two arcs of  $H$  incident with  $v$ .
- ▶ The incoming arc of  $v$  is either  $(x, v)$  if it is real, or the real arc  $(w, v)$ , where  $w$  is the relay vertex of  $(x, v)$
- ▶ Similarly, the outgoing arc of  $v$  is either  $(v, y)$  if it is real, or the real arc  $(v, w)$ , where  $w$  is the relay vertex of  $(v, y)$ .
- ▶ If  $e$  is the incoming arc of  $v$  and  $e^{-1}$  is the outgoing arc of  $v$ , we say that  $e$  is a backtrack arc of  $v$ , (in which case  $e^{-1}$  is also a backtrack arc of  $v$ )

## 2-connected graphs

- ▶ The *list of ordered wedges*  $W_1, W_2, \dots, W_k$  at  $v$  is the ordered list of all wedges with the common relay vertex  $v$  such that for  $W_i$  and  $W_j$  with  $i < j$ , the virtual path of  $W_i$  occurs before the virtual path of  $W_j$  when following  $H$  starting from  $v$

## 2-connected graphs

- ▶ The *list of ordered wedges*  $W_1, W_2, \dots, W_k$  at  $v$  is the ordered list of all wedges with the common relay vertex  $v$  such that for  $W_i$  and  $W_j$  with  $i < j$ , the virtual path of  $W_i$  occurs before the virtual path of  $W_j$  when following  $H$  starting from  $v$
- ▶ There are a few technical lemmas that determine how this list of wedges at  $v$  interact with the incoming and outgoing arcs of  $v$
- ▶ Using these we have five cases (subroutines) for the Port-Numbering procedure

## 2-connected graphs

- ▶ The *list of ordered wedges*  $W_1, W_2, \dots, W_k$  at  $v$  is the ordered list of all wedges with the common relay vertex  $v$  such that for  $W_i$  and  $W_j$  with  $i < j$ , the virtual path of  $W_i$  occurs before the virtual path of  $W_j$  when following  $H$  starting from  $v$
- ▶ There are a few technical lemmas that determine how this list of wedges at  $v$  interact with the incoming and outgoing arcs of  $v$
- ▶ Using these we have five cases (subroutines) for the Port-Numbering procedure
- ▶ We will fix  $v$ , and say  $a$  is the incoming arc of  $v$ , and  $b$  is the outgoing arc of  $v$

## 2-connected graphs

Assign  $d(v) - s(W_1)$  to  $a^{-1}$

Assign  $[d(v) - s(W_1) + 1, d(v)]$  to  $W_1$

The arc  $a$  is an isolated arc of  $v$ , and  $b$  is not.

## 2-connected graphs

Assign  $[d(v) - s(W_1) + 1, d(v)]$  to  $W_1$

Assign  $[d(v) - s(W_1) - s(W_k) + 1, d(v) - s(W_1)]$  to  $W_k$

Neither  $a$  nor  $b$  are isolated arcs of  $v$

# Periodic Traversal Result

## ► Theorem

*Let  $G$  be a  $P_3$ -free graph, with  $\delta(G) \geq 2$ . Then there exists a local orientation and a corresponding robot that will perform a periodic traversal of  $G$  with period  $\pi(n) \leq 2n - 2$*

# Future Work

- ▶ Drop the condition  $\delta(G) \geq 2$  by adding a constant number of states to the robot
- ▶ Create a procedure to assign ports for  $P_3$ -free graphs with  $\delta(G) = 1$

# Future Work

- ▶ Drop the condition  $\delta(G) \geq 2$  by adding a constant number of states to the robot
- ▶ Create a procedure to assign ports for  $P_3$ -free graphs with  $\delta(G) = 1$
- ▶ We conjecture that, using similar techniques as shown in this thesis, it is possible to create a local orientation (given some robot with a constant number of states) for 2-connected graphs that are not  $P_3$ -free
